## Math 540: Project 3

Due Thursday, March 15

1. Exercise 7.7. You should use the sensitivity relations $\frac{\partial y}{\partial \Phi}$ and $\frac{\partial y}{\partial h}$, which you computed in Problem 1 of Project 2, to construct your covariance matrix.
2. Consider the Helmholtz energy

$$
\psi(P, q)=\alpha_{1} P^{2}+\alpha_{11} P^{4}+\alpha_{111} P^{6}
$$

where $P$ is the polarization on the interval $[0,0.8]$ and $q=\left[\alpha_{1}, \alpha_{11}, \alpha_{111}\right]$ are parameters. As in Project 2, we will employ the nominal values $\alpha_{1}=-389.4, \alpha_{11}=761.3$ and $\alpha_{111}=61.5$.
(a) For $n=81,161$ and 801 equally spaced polarization values $P_{i}=(i-1) \Delta P, \Delta P=\frac{0.8}{n-1}, i=$ $1, \ldots, n$, compute the model response $\psi\left(P_{i}, q\right)$ and observations

$$
\Upsilon_{i}=\psi\left(P_{i}, q\right)+\varepsilon_{i},
$$

where $\varepsilon_{i} \stackrel{i i d}{\sim} \mathcal{N}\left(0, \sigma^{2}\right)$ with $\sigma=2.2$. In each case, compute the OLS estimate for the observation variance $\sigma^{2}$ and compare it to the true value. What do you observe?
(b) For $n=161$, use the normal equations to approximate the parameters and compare to the nominal values. Compute the covariance matrix estimate $V$ and discuss the correlation of the parameters. Discuss why global sensitivity methods, with the assumption of mutually independent parameters, may give misleading results as demonstrated in Project 2. Compute $95 \%$ confidence intervals and plot the residuals and the upper and lower confidence values in one figure. Do the intervals appear to be correct? Finally, plot the model and observations as a function of the polarization values.
3. Consider the SIR model

$$
\begin{array}{ll}
\frac{d S}{d t}=\delta N-\delta S-\gamma I S & , \quad S(0)=900 \\
\frac{d I}{d t}=\gamma I S-(r+\delta) I & , \quad I(0)=100 \\
\frac{d R}{d t}=r I-\delta R & , \quad R(0)=0
\end{array}
$$

where $\gamma, r$ and $\delta$ are each in the interval $[0,1]$. The parameter vector is $q=[\gamma, r, \delta]$
(a) Use the data in the file SIR.txt to estimate the parameters $q$ using the routine fminsearch.m. The first column contains times $t_{j}$ and the second is corresponding values $I\left(t_{j}\right)$. You can approximate the solution to the ODE system using ode45.m, as you did in Project 2.
(b) Construct the local sensitivity matrix using either finite-differences or by formulating and numerically solving the sensitivity equations. Estimate the variance $\sigma^{2}$ of the observations, compute the covariance matrix $V$, and discuss the parameter correlation. Is $V$ full rank and are your results to be expected.
(c) Using the parameter estimates and variances, use the command normpdf.m to plot the sampling distributions for each of the three parameters. Additionally, you should plot your residuals, your model fit to the data $I\left(t_{j}\right)$ and the trajectories for $S(t), I(t)$ and $R(t)$.
